Data Analysis with Python

Data Wrangling

Welcome!

By the end of this notebook, you will have learned the basics of Data Wrangling!

Table of content

Identify and handle missing values

Identify missing values

Deal with missing values

Correct data format

</li>

<li><a href="#data\_standardization">Data standardization</a></li>

<li><a href="#data\_normalization">Data Normalization (centering/scaling)</a></li>

<li><a href="#binning">Binning</a></li>

<li><a href="#indicator">Indicator variable</a></li>

Estimated Time Needed: 30 min

What is the purpose of Data Wrangling?

Data Wrangling is the process of converting data from the initial format to a format that may be better for analysis.

What is the fuel consumption (L/100k) rate for the diesel car?

Import data

You can find the “Automobile Data Set” from the following link:  
<https://archive.ics.uci.edu/ml/machine-learning-databases/autos/imports-85.data>. We will be using this data set throughout this course.

Import pandas

```
[1]: import pandas as pd  
import matplotlib.pyplot as plt
```

Reading the data set from the URL and adding the related headers.

URL of the dataset

This dataset was hosted on IBM Cloud object click [HERE](#) for free storage

```
[2]: filename = "https://s3-api.us-geo.objectstorage.softlayer.net/cf-courses-data/
      ↪CognitiveClass/DA0101EN/auto.csv"
```

Python list headers containing name of headers

```
[3]: headers = ["symboling", "normalized-losses", "make", "fuel-type", "aspiration",
      ↪"num-of-doors", "body-style",
      ↪"drive-wheels", "engine-location", "wheel-base",
      ↪"length", "width", "height", "curb-weight", "engine-type",
      ↪"num-of-cylinders",
      ↪"engine-size", "fuel-system", "bore", "stroke", "compression-ratio", "horsepower",
      ↪"peak-rpm", "city-mpg", "highway-mpg", "price"]
```

Use the Pandas method `read_csv()` to load the data from the web address. Set the parameter “names” equal to the Python list “headers”.

```
[4]: df = pd.read_csv(filename, names = headers)
```

Use the method `head()` to display the first five rows of the dataframe.

```
[5]: # To see what the data set looks like, we'll use the head() method.
      df.head()
```

```
[5]:  symboling  normalized-losses      make fuel-type aspiration num-of-doors \
0         3             ?  alfa-romero    gas      std         two

1	27	16500
2	26	16500
3	30	13950
4	22	17450

[5 rows x 26 columns]

As we can see, several question marks appeared in the dataframe; those are missing values which may hinder our further analysis.

So, how do we identify all those missing values and deal with them?

How to work with missing data?

Steps for working with missing data:

identify missing data

deal with missing data

correct data format

Identify and handle missing values

Identify missing values

Convert “?” to NaN

In the car dataset, missing data comes with the question mark “?”. We replace “?” with NaN (Not a Number), which is Python’s default missing value marker, for reasons of computational speed and convenience. Here we use the function:

to replace A by B

```
[6]: import numpy as np

# replace "?" to NaN
df.replace("?", np.nan, inplace = True)
df.head(5)
```

```
[6]:   symboling normalized-losses      make fuel-type aspiration num-of-doors \
0         3             NaN  alfa-romero      gas      std         two
1         3             NaN  alfa-romero      gas      std         two
2         1             NaN  alfa-romero      gas      std         two
3         2            164      audi      gas      std         four
4         2            164      audi      gas      std         four

   body-style drive-wheels engine-location  wheel-base  ...  engine-size  \
0  convertible         rwd         front      88.6  ...        130
1  convertible         rwd         front      88.6  ...        130
```

2	hatchback	rwd	front	94.5	...	152
3	sedan	fwd	front	99.8	...	109
4	sedan	4wd	front	99.4	...	136

	fuel-system	bore	stroke	compression-ratio	horsepower	peak-rpm	city-mpg	\
0	mpfi	3.47	2.68	9.0	111	5000	21	
1	mpfi	3.47	2.68	9.0	111	5000	21	
2	mpfi	2.68	3.47	9.0	154	5000	19	
3	mpfi	3.19	3.40	10.0	102	5500	24	
4	mpfi	3.19	3.40	8.0	115	5500	18	

	highway-mpg	price
0	27	13495
1	27	16500

3	30	13950
4	22	17450

[5 rows x 26 columns]

identify\_missing\_values

Evaluating for Missing Data

The missing values are converted to Python's default. We use Python's built-in functions to identify these missing values. There are two methods to detect missing data:

.isnull()

.notnull()

The output is a boolean value indicating whether the value that is passed into the argument is in fact missing data.

```
[14]: missing_data = df.isnull()
missing_data.head()
```

```
[14]:
```

	symboling	normalized-losses	make	fuel-type	aspiration	num-of-doors	\
0	False	False	False	False	False	False	
1	False	False	False	False	False	False	
2	False	False	False	False	False	False	
3	False	False	False	False	False	False	
4	False	False	False	False	False	False	
5	False	False	False	False	False	False	
6	False	False	False	False	False	False	
7	False	False	False	False	False	False	
8	False	False	False	False	False	False	
9	False	False	False	False	False	False	

body-style	drive-wheels	engine-location	wheel-base	...	engine-size	\
------------	--------------	-----------------	------------	-----	-------------	---

0	False	False	False	False	False	...	False
1	False	False	False	False	False	...	False
2	False	False	False	False	False	...	False
3	False	False	False	False	False	...	False
4	False	False	False	False	False	...	False
5	False	False	False	False	False	...	False
6	False	False	False	False	False	...	False
7	False	False	False	False	False	...	False
8	False	False	False	False	False	...	False
9	False	False	False	False	False	...	False

	fuel-system	bore	stroke	compression-ratio	horsepower	peak-rpm	\
0	False	False	False	False	False	False	
1	False	False	False	False	False	False	
2	False	False	False	False	False	False	
3	False	False	False	False	False	False	
4	False	False	False	False	False	False	
5	False	False	False	False	False	False	
6	False	False	False	False	False	False	
7	False	False	False	False	False	False	
8	False	False	False	False	False	False	
9	False	False	False	False	False	False	

	city-mpg	highway-mpg	price
0	False	False	False
1	False	False	False
2	False	False	False
3	False	False	False
4	False	False	False
5	False	False	False
6	False	False	False
7	False	False	False
8	False	False	False
9	False	False	True

[10 rows x 26 columns]

“True” stands for missing value, while “False” stands for not missing value.

Count missing values in each column

Using a for loop in Python, we can quickly figure out the number of missing values in each column. As mentioned above, “True” represents a missing value, “False” means the value is present in the dataset. In the body of the for loop the method “.value\_counts()” counts the number of “True” values.

```
[8]: for column in missing_data.columns.values.tolist():
      print(column)
```

```
print(missing_data[column].value_counts())
print("")
```

Based on the summary above, each column has 205 rows of data, seven columns containing missing data:

“normalized-losses”: 41 missing data

“num-of-doors”: 2 missing data

“bore”: 4 missing data

“stroke” : 4 missing data

“horsepower”: 2 missing data

“peak-rpm”: 2 missing data

“price”: 4 missing data

Deal with missing data

How to deal with missing data?

drop data a. drop the whole row b. drop the whole column

replace data a. replace it by mean b. replace it by frequency c. replace it based on other functions

Whole columns should be dropped only if most entries in the column are empty. In our dataset, none of the columns are empty enough to drop entirely. We have some freedom in choosing which method to replace data; however, some methods may seem more reasonable than others. We will apply each method to many different columns:

Replace by mean:

“normalized-losses”: 41 missing data, replace them with mean

“stroke”: 4 missing data, replace them with mean

“bore”: 4 missing data, replace them with mean

“horsepower”: 2 missing data, replace them with mean

“peak-rpm”: 2 missing data, replace them with mean

Replace by frequency:

“num-of-doors”: 2 missing data, replace them with “four”.

Reason: 84% sedans is four doors. Since four doors is most frequent, it is most likely to occur

</li>

Drop the whole row:

“price”: 4 missing data, simply delete the whole row

Reason: price is what we want to predict. Any data entry without price data cannot be used for prediction; therefore any row now without price data is not useful to us

</li>

Calculate the average of the column

```
[19]: avg_norm_loss = df["normalized-losses"].astype("float").mean(axis=0)
      print("Average of normalized-losses:", avg_norm_loss)
```

Average of normalized-losses: 122.0

Replace “NaN” by mean value in “normalized-losses” column

```
[10]: df["normalized-losses"].replace(np.nan, avg_norm_loss, inplace=True)
```

Calculate the mean value for ‘bore’ column

```
[11]: avg_bore=df['bore'].astype('float').mean(axis=0)
      print("Average of bore:", avg_bore)
```

Average of bore: 3.3297512437810943

Replace NaN by mean value

```
[13]: df["bore"].replace(np.nan, avg_bore, inplace=True)
      df.head()
```

```
[13]:  symboling normalized-losses      make fuel-type aspiration num-of-doors \
0         3          122  alfa-romero    gas      std         two
1         3          122  alfa-romero    gas      std         two
2         1          122  alfa-romero    gas      std         two
3         2          164      audi     gas      std         four
4         2          164      audi     gas      std         four

      body-style drive-wheels engine-location  wheel-base  ...  engine-size  \
0  convertible          rwd          front      88.6  ...        130
```

1	convertible	rwd	front	88.6	...	130
2	hatchback	rwd	front	94.5	...	152
3	sedan	fwd	front	99.8	...	109
4	sedan	4wd	front	99.4	...	136

	fuel-system	bore	stroke	compression-ratio	horsepower	peak-rpm	city-mpg	\
0	mpfi	3.47	2.68	9.0	111	5000	21	
1	mpfi	3.47	2.68	9.0	111	5000	21	
2	mpfi	2.68	3.47	9.0	154	5000	19	
3	mpfi	3.19	3.40	10.0	102	5500	24	
4	mpfi	3.19	3.40	8.0	115	5500	18	

	highway-mpg	price
0	27	13495
1	27	16500
2	26	16500
3	30	13950
4	22	17450

[5 rows x 26 columns]

Question #1:

According to the example above, replace NaN in “stroke” column by mean.

```
[22]: # Write your code below and press Shift+Enter to execute
avg_stroke = df["stroke"].astype("float").mean(axis=0)
df["stroke"].replace(np.nan, avg_stroke, inplace=True)
```

Double-click here for the solution.

Calculate the mean value for the ‘horsepower’ column:

```
[23]: avg_horsepower = df['horsepower'].astype('float').mean(axis=0)
print("Average horsepower:", avg_horsepower)
```

Average horsepower: 104.25615763546799

Replace “NaN” by mean value:

```
[24]: df['horsepower'].replace(np.nan, avg_horsepower, inplace=True)
```

Calculate the mean value for ‘peak-rpm’ column:

```
[25]: avg_peakrpm=df['peak-rpm'].astype('float').mean(axis=0)
print("Average peak rpm:", avg_peakrpm)
```

Average peak rpm: 5125.369458128079

Replace NaN by mean value:

```
[26]: df['peak-rpm'].replace(np.nan, avg_peakrpm, inplace=True)
```

To see which values are present in a particular column, we can use the “.value\_counts()” method:

```
[27]: df['num-of-doors'].value_counts()
```

```
[27]: four      114
      two       89
      Name: num-of-doors, dtype: int64
```

We can see that four doors are the most common type. We can also use the “.idxmax()” method to calculate for us the most common type automatically:

```
[31]: df['num-of-doors'].value_counts().idxmax()
```

```
[31]: 'four'
```

The replacement procedure is very similar to what we have seen previously

```
[32]: #replace the missing 'num-of-doors' values by the most frequent
      df["num-of-doors"].replace(np.nan, "four", inplace=True)
```

Finally, let’s drop all rows that do not have price data:

```
[33]: # simply drop whole row with NaN in "price" column
      df.dropna(subset=["price"], axis=0, inplace=True)

      # reset index, because we dropped two rows
      df.reset_index(drop=True, inplace=True)
```

```
[34]: df.head()
```

```
[34]:   symboling  normalized-losses      make fuel-type aspiration num-of-doors \
0         3         122  alfa-romero    gas      std         two
1         3         122  alfa-romero    gas      std         two
2         1         122  alfa-romero    gas      std         two
3         2         164      audi     gas      std         four
4         2         164      audi     gas      std         four

      body-style drive-wheels engine-location  wheel-base  ...  engine-size  \
0  convertible         rwd         front      88.6  ...      130

4	mpfi	3.19	3.40	8.0	115	5500	18

	highway-mpg	price
0	27	13495
1	27	16500
2	26	16500
3	30	13950
4	22	17450

[5 rows x 26 columns]

Good! Now, we obtain the dataset with no missing values.

Correct data format

We are almost there!

The last step in data cleaning is checking and making sure that all data is in the correct format (int, float, text or other).

In Pandas, we use

.dtype() to check the data type

.astype() to change the data type

Lets list the data types for each column

```
[35]: df.dtypes
```

```
[35]: symboling          int64
normalized-losses      object
make                   object
fuel-type              object
aspiration             object
num-of-doors           object
body-style             object
drive-wheels           object
engine-location        object
wheel-base            float64
length                float64
width                 float64
height                float64
curb-weight            int64
engine-type            object
num-of-cylinders       object
engine-size            int64
fuel-system            object
```

```

bore                object
stroke              object
compression-ratio   float64
horsepower          object
peak-rpm            object
city-mpg            int64
highway-mpg         int64
price               object
dtype: object

```

As we can see above, some columns are not of the correct data type. Numerical variables should have type 'float' or 'int', and variables with strings such as categories should have type 'object'. For example, 'bore' and 'stroke' variables are numerical values that describe the engines, so we should expect them to be of the type 'float' or 'int'; however, they are shown as type 'object'. We have to convert data types into a proper format for each column using the "astype()" method.

Convert data types to proper format

```

[36]: df[["bore", "stroke"]] = df[["bore", "stroke"]].astype("float")
      df[["normalized-losses"]] = df[["normalized-losses"]].astype("int")
      df[["price"]] = df[["price"]].astype("float")
      df[["peak-rpm"]] = df[["peak-rpm"]].astype("float")

```

Let us list the columns after the conversion

```

[37]: df.dtypes

```

```

[37]: symboling          int64
      normalized-losses   int64
      make                object
      fuel-type           object
      aspiration           object
      num-of-doors        object
      body-style           object
      drive-wheels        object
      engine-location      object
      wheel-base          float64
      length              float64
      width                float64
      height              float64
      curb-weight          int64
      engine-type          object
      num-of-cylinders     object
      engine-size          int64
      fuel-system          object
      bore                 float64
      stroke               float64
      compression-ratio    float64

```

```
horsepower      object
peak-rpm       float64
city-mpg        int64
highway-mpg     int64
price          float64
dtype: object
```

Wonderful!

Now, we finally obtain the cleaned dataset with no missing values and all data in its proper format.

## Data Standardization

Data is usually collected from different agencies with different formats. (Data Standardization is also a term for a particular type of data normalization, where we subtract the mean and divide by the standard deviation)

What is Standardization?

Standardization is the process of transforming data into a common format which allows the researcher to make the meaningful comparison.

## Example

Transform mpg to L/100km:

In our dataset, the fuel consumption columns “city-mpg” and “highway-mpg” are represented by mpg (miles per gallon) unit. Assume we are developing an application in a country that accept the fuel consumption with L/100km standard

We will need to apply data transformation to transform mpg into L/100km?

The formula for unit conversion is

$$\text{L/100km} = 235 / \text{mpg}$$

We can do many mathematical operations directly in Pandas.

```
[38]: df.head()
```

```

Data Normalization

Why normalization?

Normalization is the process of transforming values of several variables into a similar range. Typical normalizations include scaling the variable so the variable average is 0, scaling the variable so the variance is 1, or scaling variable so the variable values range from 0 to 1

Example

To demonstrate normalization, let's say we want to scale the columns "length", "width" and "height"

Target: would like to Normalize those variables so their value ranges from 0 to 1.

Approach: replace original value by (original value)/(maximum value)

```
[44]: # replace (original value) by (original value)/(maximum value)
df['length'] = df['length']/df['length'].max()
df['width'] = df['width']/df['width'].max()
df.head()
```

```
[44]:   symboling  normalized-losses      make fuel-type aspiration \
0         3         122  alfa-romero      gas      std
1         3         122  alfa-romero      gas      std
2         1         122  alfa-romero      gas      std
3         2         164      audi      gas      std
4         2         164      audi      gas      std

   num-of-doors  body-style drive-wheels engine-location  wheel-base  ... \
0         two  convertible      rwd      front      88.6  ...
1         two  convertible      rwd      front      88.6  ...
2         two   hatchback      rwd      front      94.5  ...
3         four      sedan      fwd      front      99.8  ...
4         four      sedan      4wd      front      99.4  ...

   fuel-system  bore  stroke  compression-ratio  horsepower  peak-rpm  city-mpg  \
0      mpfi  3.47   2.68           9.0         111   5000.0      21
1      mpfi  3.47   2.68           9.0         111   5000.0      21
2      mpfi  2.68   3.47           9.0         154   5000.0      19
3      mpfi  3.19   3.40          10.0         102   5500.0      24
4      mpfi  3.19   3.40           8.0         115   5500.0      18

   highway-L/100km  price  city-L/100km
0      8.703704  13495.0    11.190476
1      8.703704  16500.0    11.190476
2      9.038462  16500.0    12.368421
3      7.833333  13950.0     9.791667
4     10.681818  17450.0    13.055556
```

[5 rows x 27 columns]

Questiont #3:

According to the example above, normalize the column “height”.

```
[46]: # Write your code below and press Shift+Enter to execute
df['height'] = df['height']/df['height'].max()
df[["length","width","height"]].head()
```

```
[46]:      length      width      height
0  0.811148  0.890278  0.816054
1  0.811148  0.890278  0.816054
2  0.822681  0.909722  0.876254
3  0.848630  0.919444  0.908027
4  0.848630  0.922222  0.908027
```

Double-click here for the solution.

Here we can see, we’ve normalized “length”, “width” and “height” in the range of [0,1].

Binning

Why binning?

Binning is a process of transforming continuous numerical variables into discrete categorical ‘bins’, for grouped analysis.

Example:

In our dataset, “horsepower” is a real valued variable ranging from 48 to 288, it has 57 unique values. What if we only care about the price difference between cars with high horsepower, medium horsepower, and little horsepower (3 types)? Can we rearrange them into three ‘bins’ to simplify analysis?

We will use the Pandas method ‘cut’ to segment the ‘horsepower’ column into 3 bins

Example of Binning Data In Pandas

Convert data to correct format

```
[47]: df["horsepower"]=df["horsepower"].astype(int, copy=True)
```

Lets plot the histogram of horspower, to see what the distribution of horsepower looks like.

```
[48]: %matplotlib inline
import matplotlib as plt
from matplotlib import pyplot
plt.pyplot.hist(df["horsepower"])

# set x/y labels and plot title
plt.pyplot.xlabel("horsepower")
plt.pyplot.ylabel("count")
plt.pyplot.title("horsepower bins")
```

```
[48]: Text(0.5, 1.0, 'horsepower bins')
```

We would like 3 bins of equal size bandwidth so we use numpy's `linspace(start_value, end_value, numbers_generated)` function.

Since we want to include the minimum value of horsepower we want to set `start_value=min(df["horsepower"])`.

Since we want to include the maximum value of horsepower we want to set `end_value=max(df["horsepower"])`.

Since we are building 3 bins of equal length, there should be 4 dividers, so `numbers_generated=4`.

We build a bin array, with a minimum value to a maximum value, with bandwidth calculated above. The bins will be values used to determine when one bin ends and another begins.

```
[49]: bins = np.linspace(min(df["horsepower"]), max(df["horsepower"]), 4)
      bins
```

```
[49]: array([ 48.          , 119.33333333, 190.66666667, 262.          ])
```

We set group names:

```
[50]: group_names = ['Low', 'Medium', 'High']
```

We apply the function “cut” to determine what each value of “df[‘horsepower’]” belongs to.

```
[51]: df['horsepower-binned'] = pd.cut(df['horsepower'], bins, labels=group_names,
    ↪include_lowest=True )
df[['horsepower', 'horsepower-binned']].head(20)
```

```
[51]:      horsepower horsepower-binned
0           111             Low
1           111             Low
2           154           Medium
3           102             Low
4           115             Low
5           110             Low
6           110             Low
7           110             Low
8           140           Medium
9           101             Low
10          101             Low
11          121           Medium
12          121           Medium
13          121           Medium
14          182           Medium
15          182           Medium
16          182           Medium
17           48             Low
18           70             Low
19           70             Low
```

Lets see the number of vehicles in each bin.

```
[52]: df["horsepower-binned"].value_counts()
```

```
[52]: Low          153
Medium          43
High             5
Name: horsepower-binned, dtype: int64
```

Lets plot the distribution of each bin.

```
[53]: %matplotlib inline
import matplotlib as plt
from matplotlib import pyplot
pyplot.bar(group_names, df["horsepower-binned"].value_counts())

# set x/y labels and plot title
plt.pyplot.xlabel("horsepower")
plt.pyplot.ylabel("count")
plt.pyplot.title("horsepower bins")
```

```
[53]: Text(0.5, 1.0, 'horsepower bins')
```

Check the dataframe above carefully, you will find the last column provides the bins for “horsepower” with 3 categories (“Low”, “Medium” and “High”).

We successfully narrow the intervals from 57 to 3!

Bins visualization

Normally, a histogram is used to visualize the distribution of bins we created above.

```
[54]: %matplotlib inline
import matplotlib as plt
from matplotlib import pyplot

a = (0,1,2)

# draw histogram of attribute "horsepower" with bins = 3
plt.pyplot.hist(df["horsepower"], bins = 3)

# set x/y labels and plot title
plt.pyplot.xlabel("horsepower")
plt.pyplot.ylabel("count")
plt.pyplot.title("horsepower bins")
```

```
[54]: Text(0.5, 1.0, 'horsepower bins')
```

The plot above shows the binning result for attribute “horsepower”.

Indicator variable (or dummy variable)

What is an indicator variable?

An indicator variable (or dummy variable) is a numerical variable used to label categories. They are called ‘dummies’ because the numbers themselves don’t have inherent meaning.

Why we use indicator variables?

So we can use categorical variables for regression analysis in the later modules.

Example

We see the column “fuel-type” has two unique values, “gas” or “diesel”. Regression doesn’t understand words, only numbers. To use this attribute in regression analysis, we convert “fuel-type” into indicator variables.

We will use the panda’s method ‘get\_dummies’ to assign numerical values to different categories of fuel type.

```
[55]: df.columns
```

```
[55]: Index(['symboling', 'normalized-losses', 'make', 'fuel-type', 'aspiration',  
          'num-of-doors', 'body-style', 'drive-wheels', 'engine-location',  
          'wheel-base', 'length', 'width', 'height', 'curb-weight', 'engine-type',  
          'num-of-cylinders', 'engine-size', 'fuel-system', 'bore', 'stroke',
```

```
'compression-ratio', 'horsepower', 'peak-rpm', 'city-mpg',
'highway-L/100km', 'price', 'city-L/100km', 'horsepower-binned'],
dtype='object')
```

get indicator variables and assign it to data frame “dummy\_variable\_1”

```
[56]: dummy_variable_1 = pd.get_dummies(df["fuel-type"])
dummy_variable_1.head()
```

```
[56]:   diesel  gas
0       0    1
1       0    1
2       0    1
3       0    1
4       0    1
```

change column names for clarity

```
[57]: dummy_variable_1.rename(columns={'fuel-type-diesel':'gas', 'fuel-type-gas':
↳ 'diesel'}, inplace=True)
dummy_variable_1.head()
```

```
[57]:   diesel  gas
0       0    1
1       0    1
2       0    1
3       0    1
4       0    1
```

We now have the value 0 to represent “gas” and 1 to represent “diesel” in the column “fuel-type”. We will now insert this column back into our original dataset.

```
[58]: # merge data frame "df" and "dummy_variable_1"
df = pd.concat([df, dummy_variable_1], axis=1)

# drop original column "fuel-type" from "df"
df.drop("fuel-type", axis = 1, inplace=True)
```

```

[5 rows x 29 columns]

The last two columns are now the indicator variable representation of the fuel-type variable. It's all 0s and 1s now.

Question #4:

As above, create indicator variable to the column of “aspiration”: “std” to 0, while “turbo” to 1.

```
[61]: # Write your code below and press Shift+Enter to execute
dummy_variable_2 = pd.get_dummies(df['aspiration'])
dummy_variable_2.rename(columns={'std':'aspiration-std', 'turbo':
    ↳'aspiration-turbo'}, inplace=True)

dummy_variable_2.head()
```

```
[61]: aspiration-std aspiration-turbo
0          1          0
1          1          0
2          1          0
3          1          0
4          1          0
```

[Double-click here for the solution.](#)

Question #5:

Merge the new dataframe to the original dataframe then drop the column ‘aspiration’

```
[65]: # Write your code below and press Shift+Enter to execute
df = pd.concat([df, dummy_variable_2], axis=1)
# df.drop("aspiration", axis = 1, inplace=True)
df.head()
```

```
